Weeds in my infield dirt

Is there a good chemical strategy for control of unwanted vegetation on baseball infields? We are currently using Glyphosate and Surflan. Is Casoron an option?

This is a good question where careful consideration should be given when herbicides are being used. Yes, there are herbicides labeled for use in turf, ornamentals, and non-crop areas that can effectively remove and prevent weeds on skin infields; however, none of the products are specifically labeled for use on skin infields.

Remember that pesticides are granted registration partially on how they are used. I have yet to find a pesticide specifically used for baseball skin infields. From my perspective I suggest that you do not use any pre or post emergent herbicides, except glyphosate, on the infield skin because of the intimate contact that players have with the infield dirt surface. Glyphosate offers a quick burn down with no residual soil affects so I still consider it a low-risk pesticide for use on infield skin areas.

Even though preemergence herbicides like oryzalin, prodiamine, or imazapyr are often recommended in turf, ornamental, and non-crop areas they are not specifically cited for use on baseball infield skin areas. The same product used in a turf area may react differently in a baseball skin because there is no organic matter in the infield dirt to tie up the herbicide or to break it down by feeding microbes.

Another group of herbicides that provide total vegetation control are often considered for skin areas but should be avoided. Casoron (dichlobenil) can move with surface water so I would also exclude it from my baseball infield skin list because of its potential to run off the skin area and damage the surrounding turfgrass. Pramitol (prometon) is labeled for use around buildings, storage areas, roadways, airports, highway medians, lumberyards, pipelines, fences, recreational areas, and similar areas where total weed and grass control is needed. It is described as a bare ground herbicide and it will allow nothing to grow for a year. It has a danger signal word and has the potential to be washed from the dirt area and damage the surrounding grass. It is another one I would eliminate from my infield skin management program.

So what can you use to keep weeds out of the infield skin? For existing weeds use glyphosate herbicide. As an alternative vinegar and essential oil-based products seldom have a place for weed control in lawns, but they are ideally suited to quickly burn down the bare soils found on baseball infields. A 20% vinegar solution applied during the heat of the day will kill just about any plant it touches.

The real key to keeping weeds out of the infield is to not neglect field grooming. Unfortunately, many fields are abandoned at summer’s end and weeds take over. Field grooming once a week until frost begins is a good way to keep the fields from turning to weeds. More silt and clay equals more weed growth. Avoid blowing weed seeds into the infield skin. Infields in the Midwest constructed with 4 inches of ag lime help reduce weeds because of the unfavorable alkaline growing condition, but when grooming completely stops weeds like crabgrass, goosegrass, foxtail and knot weed can establish. Young weeds can be rouged out by the tines of various windrow weeds for easy clean up. Sometimes a little moisture helps remove the weeds but don’t schedule this type of work when the field is wet. Operate the equipment slowly to window weeds for easy clean up. Many high school coaches that have to manage their own fields are switching to grass between home and first and home and third; less dirt to manage and fewer lips in the critical section of the field.

Players come into intimate contact with the dust and wet soils found on baseball/softball infields. Unnecessary exposure of players to pesticides is what causes mistrust among concerned parents. If you think you are doing something wrong then you probably are! Some vinegar and a good grooming machine go a long way to making safe and attractive infields.
